

Setup Your **Workspace**

Today is about preparing your tools. Think of it like buying tools before building a house. **Time Limit: 2 Hours Only.**

Time Discipline Matters

With final exams starting on March 5th, you must strictly follow the 2-hour rule. No overthinking. No delay.

Hour 1

Read + Watch setup videos

Hour 2

Install + Practice

Step 1: Install Python

The Brain

Your computer does NOT understand Python by default. We must install the "brain" that translates Python into machine language.

- Go to `python.org`
- Download the latest version for your OS (Windows/Mac).
- Run the downloaded installer.

Critical Installation Step

Add Python to PATH

When installing Python, look at the bottom of the first installer window.

- Check the box: "Add Python to PATH"
- Then click: "Install Now"
- Wait until installation completes.

⚠ Warning: If you skip this step, Python will not work in your terminal.

Step 2: Install VS Code

The Canvas

You need a professional code editor to write and manage your projects effectively.

- Go to code.visualstudio.com
- Download the installer.
- Install normally with default settings.
- Open VS Code after installation finishes.

Install Python Extension

Now we need to ensure VS Code understands Python syntax and commands.

1. Extensions

Click the Extensions icon on the left side panel of VS Code.

2. Search

Type "Python" into the search bar at the top of the panel.

3. Install

Find the official extension by Microsoft and click Install.

Step 3: Create Folder

Organize Your Work

A dedicated workspace keeps your code organized and easy to run.

- Go to your Desktop.
- Create a new folder and name it exactly:
`Python_30_Days`
- Open VS Code.
- Go to **File** → **Open Folder** and select this new folder.

Create Python File

Your First Script

Inside VS Code, we will create the file where you will write your code.

- Click the **New File** icon in the explorer pane.
- Name it exactly:

`day1.py`

- The `.py` extension tells the computer this is a Python executable file.

Write Your First Code

Inside `day1.py`, type the following exactly as shown:

```
print("Hello, World!")
```

 *Do not change brackets or quotation marks.*

Step 4: Open Terminal

Talk to the Computer

The terminal is the command line interface where you execute your scripts.

- In VS Code, look at the Top Menu.
- Click **Terminal** → **New Terminal**.
- A panel will open at the bottom of your screen.
- This is where you will issue commands to run your code.

The screenshot shows a terminal window titled "linux@linux: ~" with a dark purple background. The window displays the manual page for the "resize" command. The content is as follows:

```
linux@linux: ~  
RESIZE(1) X Window System RESIZE(1)  
NAME  
    resize - set environment and terminal settings to current xterm window size  
SYNOPSIS  
    resize [ -v | -u | -c ] [ -s [ row col ] ]  
DESCRIPTION  
    Resize prints a shell command for setting the appropriate environment variables to indicate the  
    current size of xterm window from which the command is run.  
    Resize determines the command through several steps:  
    · first, it finds the name of the user's shell program. It uses the SHELL variable if set, oth-  
      erwise it uses the user's data from /etc/passwd.  
    · then it decides whether to use Bourne shell syntax or C-Shell syntax. It uses a built-in ta-  
      ble of known shells, which can be overridden by the -u and -c options.  
    · then resize asks the operating system for the terminal settings. This is the same information  
      which can be manipulated using stty.  
    · then resize asks the terminal for its size in characters. Depending on whether the "-s" option  
      is given, resize uses a different escape sequence to ask for this information.  
    · at this point, resize attempts to update the terminal settings to reflect the terminal win-  
      dow's size in pixels.  
Manual page resize(1) line 1 (press h for help or q to quit)
```

Run Your Program

In the terminal panel, type the correct command for your operating system and press **Enter**.

Type this command:

```
python day1.py
```

Type this command:

```
python3 day1.py
```

Expected Output

Hello,
World!

Congratulations! 🎉

If everything is correct, you will see the message output in your terminal.

You have officially written and executed your first computer program.

Day 1 Mission Complete

Today you successfully:

- ✓ Installed Python and configured the PATH variable.
- ✓ Installed VS Code and the necessary Python extension.
- ✓ Set up your workspace with a dedicated folder structure.
- ✓ Ran your first program via the command line terminal.

This is your first real step into programming.
